INTRODUCTION

This service manual was prepared for use by Authorized Warranty Stations and contains service information for Marantz Model 4400 Stereo 2+Quadradiat 4 Receiver.

Servicing information and voltage data included in this manual are intended for use by the knowledgeable and experienced technician only. All instruction should be read carefully. No attempt should be made to proceed without a good understanding of the operation in the receiver.

The parts list provides information by which replacement parts may be ordered from the Marantz Company. A simple description is included for parts which can be usually be obtained through local suppliers.

1. SERVICE NOTES

As can be seen from the circuit diagram, the chassis of Model 4400 consists of the following module units. Each unit mounted on a printed circuit board is described within the square enclosed by a bold dotted line on the circuit diagram.

1. FM Front End	mounted on P.W. Board, P100
2. AM Tuner	mounted on P.W. Board, P150
3. FM IF Amplifier	mounted on P.W. Board, P200
4. MPX Stereo Decoder, Noise and DC Amplifier	mounted on P.W. Board, P300
5. Phono Amplifier	mounted on P.W. Board, P400
6. Vari-Matrix	mounted on P.W. Board, P500
7. Dolby Unit	mounted on P.W. Board, P600
8. Power Amplifier	mounted on P.W. Board, P700
9. Power Supply	mounted on P.W. Board, P800
10. Scope Amplifier	mounted on P.W. Board, P900
11. FM CAL	mounted on P.W. Board, PC01
12. Tone Amplifier	mounted on P.W. Board, PD01
13. Buffer and Pre-Amplifier	mounted on P.W. Board, PE01
14. Tone Control and Diode Matrix Unit	mounted on P.W. Board, PF01
15. Balance Control Unit	mounted on P.W. Board, PG01
16. Filter Amplifier	mounted on P.W. Board, PH01
17. 400Hz Oscillator and Meter Driver	mounted on P.W. Board, PL01
18. Phase Convertor	mounted on P.W. Board, PM01
19. Speaker Protector	mounted on P.W. Board, PN01
20. Fuse Unit	mounted on P.W. Board, PP01
21. Switch Unit	mounted on P.W. Board, PS01
22. Switch Unit	mounted on P.W. Board, PT01
23. FM De-emphasis	mounted on P.W. Board, PU01
24. Dolby Terminal	mounted on P.W. Board, PV01
25. Head Phones	mounted on P.W. Board, PW01
26. Meter Lamp	mounted on P.W. Board, PX01
27. Selector Lamps	mounted on P.W. Board, PY01
28. Dial Lamps	mounted on P.W. Board, PZ01

2. AM TUNER

The AM TUNER portion of the 4400 is composed of one IC circuit (including RF amplifier, local oscillator, mixer, IF amplifier, detector, and a signal strength indicator amplifier) and one transistor amplifier to amplify the detected audio signals.

All components except the Tuning capacitor and ferrite bar antenna are mounted on printed circuit board P150.

The AM signals induced in a ferrite bar antenna are applied to the input of RF amplifier

(pin ①) through a capacitor of C151 and amplified to the level required for overcoming the conversion noises, thus giving good S/N performance. The tuned circuits inserted in both output and input circuit of RF amplifier assure very high image and spurious rejection performance.

Thus amplified and selected AM signals are then applied to one input of Mixer section (pin ⑥) through a coupling capacitor C158, while the local oscillator voltage is injected to the other input of the section (pin ⑤) through a capacitor C157. Then both the AM signal and oscillator voltage are mixed and converted into 455KHz intermediate frequency. The resulting IF signal is applied to the first IF transformer L153 consisting of one ceramic filter and two tuned circuits.

The output of L153 is led to the IF amplifier's input (pin ⑦) through a coupling capacitor C169 and amplified to sufficient level to drive the detector. The output of IF amplifier (pin ⑧) is led to the detector's input (pin ⑫) through IF filter L154. The detected audio signal derived from pin ⑪ is filtered and amplified and final audio output is obtained from the collector of H152 and applied to the TAPE MONITOR OUT jacks through the function switch.

The DC component of the detected IF signal is used as a AGC voltage to control emitter current of RF and IF amplifiers through the resistors R154 and R155. A part of the DC component is also applied to the signal strength indication amplifier incorporated in the IC. The output appears at pin ⑭ and is level adjusted by R152, indicated on the display scope H011 through vertical scope amplifier.

2.1 Suggestion for AM Tuner trouble shooting

Check for broken AM bar antenna, next try to tune station by rotating fly-wheel tuning knob slowly and observe the spot on the oscilloscope whether it deflects up and down or not. If the spot moves up and down as you tune past each station, no failure may exist in the stages at least preceding final IF transformer L154. Next connect a oscilloscope to the test point ③ or J157 and check for audio signals with the tuning meter deflected. If the signal strength does not deflect, check the local oscillator circuit. Normal oscillator voltage at the hot end of the oscillator tuning capacitor is about 1.5 or 3 volts, varying with tuning capacitor position. When measuring oscillator voltage use an RF VTVM; no circuit tester gives correct indication. If the local oscillator voltage is normal, check all voltage distribution in the AM circuits by using a DC VTVM and compare the measured values with those given in the schematic diagram.

3. FM TUNER

3.1 RF and IF Circuit

The FM Tuner section of the Model 4400 is divided into five functional blocks: FM Front End, IF Amplifier, Detector, Muting Control and MPX Stereo Decoding Circuit.

FM signals induced by a FM antenna are led to FM antenna coil L101 through a Balun coil. These signals are then applied to the FET RF amplifier which in turn applies its output to the next FET Mixer H102 through the triple tuned highly selective circuits. The FET Mixer converts its input signal into 10.7 MHz intermediate frequency and amplifies it at the same time. The H103 is a local oscillator and its output is injected into the source of the FET Mixer, the injection voltage is about 700 mV. The 10.7 MHz front end output is fed to the next IF amplifier unit through a coaxial cable.

The IF amplifier unit consists of seven IF amplifier stages and one AGC amplifier stage. Eight ceramic filters are also used to obtain high selectivity and four symmetrical diode limiter stages are employed for the best limiting characteristics, improved capture ratio and good AM suppression.

A part of FM Front End output is applied to the AGC amplifier H209 and its rectified output is fed back to the gate of FET RF amplifier to decrease the gain with increased signal strength.

The signals required for multipath indication are obtained from the five stages of IF amplifiers through coupling capacitors C252, C211, C214, C223 and C228 respectively and

rectified by five pair of full wave diode circuits. Thusly obtained AM components from the FM signal are appropriately mixed and applied to the vertical amplifier for multipath display.

The IF signal sufficiently amplified through each stage of IF amplifier is finally applied to the Detector Amplifier H208. The detected audio output is fed to the buffer amplifier H210 and its buffered output is fed to; (a) noise amplifier H310 through resistor R378 and capacitor C333, (b) QUADRADIAL OUTPUT Jack on the rear panel through resistor R379, (c) MPX stereo decoding IC (H321) through R301 and H301.

3.2 Audio Muting and Stereo Mode Auto-Selecting Circuit

The muting circuit consisting of all solid-state electrical switching has been incorporated in the Model 4400. Three inputs control the muting function. The first is related to signal strength, the second to the noise condition at the detector and the third is derived from the DC component of the detector output. These inputs are properly matrixed and gated to provide muting free from noise and transients.

The first input of DC voltage obtained by rectifying a part of IF output signal from the H205 and H206 is applied to the base of H308 and turns it on, if the IF output is greater than predetermined level (muting threshold level). When the H308 is turned on the H309 is turned off, allowing the emitter-collector resistance increasing and the collector voltage rises about 9V. The increased collector voltage increases the gate bias voltage and turns on the switching FET H301, decreasing the source-drain resistance to near zero ohm and allowing the audio signal applied to the source to flow to the pin ② of decoding IC through the source-drain path.

When the input signal is lower than predetermined level, the DC output obtained is small and can not turn on the H308, thus the H308 keeps its turn-off stage and this makes H309 turn on, decreasing the collector voltage and turning off H301. Thus no audio signals can pass through the FET. This is the fundamental principle of the muting operation but for more elaborate muting operation the second and the third inputs are necessary.

The second input is used to protect the muting operation and MPX stereo beacon lamps from misoperation due to undesirable noises. The high frequency noises included in the detected audio signals are separated by a small capacitor C333 and amplified by the noise amplifier transistor H310 and its output is rectified by the two diodes. The rectified DC output is proportional to the noise components in the audio signals.

When there are excessive noises in the audio signals such as obtained with a station incorrectly tuned in, the rectified DC output turns on the transistor H311, decreasing the emitter-collector resistance to zero. This means the collector of H309 is short-circuited to the ground, therefore the H301 is turned off and any audio signals having excessive high frequency noises can not go through the FET's source-drain path.

The transistor H317, also, turns off when transistor H309 or H311 turns on, and turns on the transistor H303 connected to pin ⑧ on the MPX decoding IC. Pin ⑧ is therefore grounded equivalently to set the IC in the monaural mode of operation. This prevent misoperation due to undesirable noises when the FM tuner is out of tuning.

The third input is obtained from the FM discriminator circuit. The DC output so called "S" curve is applied to the gate of H312 through a resistor R281 and dividing network (R361 & R362). The DC output is zero with a station correctly tuned in, but will vary from negative to positive values or vice versa when the tuning point is deviated toward either plus or minus frequency from the correct tuning frequency.

When the DC output is increased to a greater level than that of predetermined, the increased source potential of H312 makes the transistor H315 turn on (this means the collector of H309 is short-circuited to the ground), ... H301 turn off, ... H317 turn off, ... H303 turn on. This grounds pin ⑧ of the MPX stereo decoding IC, therefore the decoder is set in the monaural mode of operation and the stereo indicator lamp turns off. When the DC output is increased to the negative predetermined level, the decreased source potential turns off the H313 which in turn makes the H314 turn on (This means the collector of H309 is short-circuited to the ground).

The subsequently changes are exactly the same as that just described above.

Thus when the tuning is shifted or deviated to the certain frequencies in which undesirable noisy side-audio signals are produced, both muting and monaural/stereo Switching Transistor H303 are operated automatically and open the circuits.

With the station correctly tuned in, the bias current of the FET H312 is adjusted so that both transistor H314 and H315 are not turned on, giving no effect on the transistor H309.

3.3 MPX Stereo Decoding Circuit

The stereo composite signal from the buffer amplifier undergoes a phase compensation by R301 and C301, is applied through the muting switching FET H301 to the input terminal pin ②, of the MPX stereo decoding IC H321 on a PLL (Phase Locked Loop) basis, and decoded into the left and right stereo signals, which become available at pins ④ and ⑤ respectively.

These decoded left and right stereo audio signals are introduced through a low pass filter composed of L301 to L304 and C311 to C320 for elimination of undesirable residual switching signal and through a de-emphasis network consisting of R325, R326, C321 and C322, into the npn-pnp direct coupled audio amplifier, where the signals are amplified to a required level for the output from J311 and J313. From these jacks, the audio signals are led to the TAPE MONITOR OUT jacks through the function switch. Figure 1 presents an internal block diagram showing the functions of the PLL basis MPX stereo decoding IC HA1156. The input stereo composite signal, amplified by the audio amplifier, is delivered to the phase detectors PD-1 and PD-2. A part of the stereo composite signal is also applied to the stereo decoder section.

The VCO (Voltage Control Oscillator) produces a free run oscillation in the neighborhood of 76KHz with the time constant determined by a capacitor C305 and resistors R311 and R312 set on the outside of pin ⑭. The VCO output has its frequency divided into 19KHz through the two stages of the frequency divider (DIV-1 & DIV-2), and is reverted to the phase detector PD-1, which contains two input terminals designed to produce an output in proportion to the product of the two input signals. The signal applied to one of the inputs of PD-1 is the 19KHz square wave formed through frequency division of the 76KHz VCO output signal by the two stages of the frequency divider DIV-1 and DIV-2, and the 19KHz pilot signal included in the stereo composite signal as a reference signal is applied to the other input. Therefore, the output of PD-1 which has passed through the low pass filter LPF-1 provides DC output voltage in proportion to the phase variance between the two inputs. This DC output voltage is amplified by

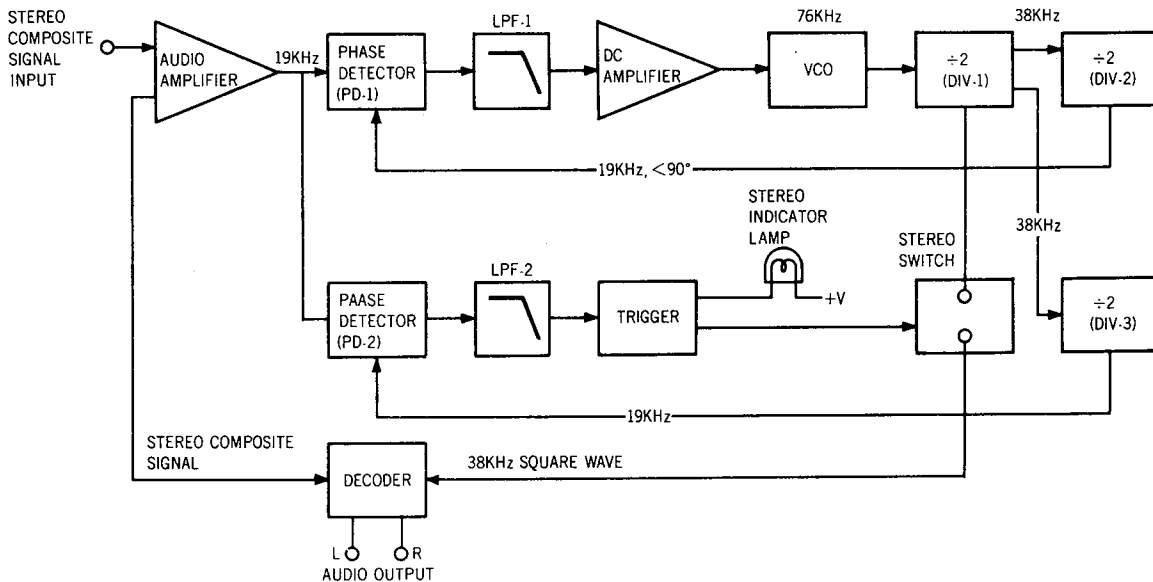

Figure 1. Block Diagram of the HA1156

the DC amplifier, and supplied to the 76KHz VCO as a control voltage. This means that the output frequency and phase of the VCO have been phase-locked to the input pilot signal. The 38KHz sub-carrier reproduced by PLL as stated above is delivered through the stereo switch to the stereo decoder section as a switching signal, thus driving the decoder section. One of the inputs of PD-2 is given the 19KHz resulting from the frequency division completed by DIV-1 and DIV-3, whereas the other input gets the 19KHz output contained in the composite signal, and the output is provided with a DC output in proportion to the amplitude of the pilot signal.

This DC output is furnished through LPF-2 to the trigger amplifier which drives the stereo indicator lamp and stereo switch. Therefore, insufficient supply of the pilot signal results in failure to light the stereo indicator and to turn on the stereo switch located in the path of the 38KHz switching signal, thereby avoiding a wrong stereo operation. H303 attached on the outside of pin ⑧ is a switching transistor for automatic monaural-stereo switchover. When the intensity of an incoming signal from an FM station is weaker than a predetermined level, this H303 is turned on and pin ⑧ is grounded, thereby developing a condition for monaural reception. For a forced monaural operation, switch the MODE switch to "MONO," and H303 comes into an "On" condition with the positive bias voltage applied to the base, and pin ⑧ is grounded, thereby establishing monaural operation. The transistor H302 connected externally to pin ⑭ is intended to stop the 76KHz oscillation of the VCO which interferes an AM signal during the reception of an AM station. When the function switch is set to "AM" position, a positive bias is charged on the base of H302, H302 is turned on, and pin ⑭ is grounded. Thus, the oscillation of the VCO is stopped, ending the interference with AM reception.

3.4 Suggestion for Trouble Shooting of FM Tuner

3.4.1 Symptom: No FM Reception

Turn on the POWER switch.

Turn on (depress) two SCOPE DISPLAY switches "ON" and "TUNING".

First try to tune to some FM stations. (Before this tuning, make sure that the spot on the scope display is centered by following the instructions of Step 22-1 to -5 in Section 22, the "SCOPE DISPLAY ALIGNMENT".)

Rotate the fly-wheel tuning knob slowly and observe the spot on the oscilloscope whether it follows an approximately rectangular path as you tune past each station or not. If it moves as described, the tuner circuits preceding the discriminator circuit may have no failure. If not, there would be some defects in the front end or IF amplifier stages, or oscilloscope circuits. To localize the defects in the former case, check FM local oscillator circuit, using RF VTVM. The normal local oscillator voltage is one or two volts (rms) at the tuning capacitor, depending on the tuning capacitor position. If the local oscillator voltage is normal, next check all voltage distribution in the front end and IF amplifier stages and compare them with those shown in the circuit diagram.

For localizing the defects in the latter case it is one of methods to apply an audio signal to the "CD-4/AUX" INPUTS jacks (FRONT L or R) on the rear panel with the "AUDIO" SCOPE DISPLAY switch, SELECTOR switch "CD-4/AUX".

The detected audio signals can also be checked by depressing the SCOPE DISPLAY switch "AUDIO" if scope circuit operate without any defects.

3.4.2 Symptom: No Stereo Separation

First check the "MODE" switch is in normal 2 CH position. Connect a FM RF signal generator output modulated by a stereo modulator to the rear FM antenna terminals, and check the stereo beacon is turned on or not. If not turned on, check for 19KHz VCO output signal (J310), using an oscilloscope and a frequency counter.

4. PHONO AND PRE-AMPLIFIER

Signals from the PHONO jacks are applied to the phono-amplifier mounted on P400. The amplified and RIAA equalized phono signals and signals from the tuner section, CD-4/AUX and

TAPE MONITOR IN jacks are applied to the SELECTOR switch which, in turn, leads the selected signals to the TAPE MON. switch and TAPE MONITOR OUT jacks. Applied to the other section of the TAPE MON. switch are signals from the TAPE MONITOR IN jacks. The TAPE MON. switch selects the signals from the SELECTOR switch or those from the TAPE MONITOR IN jacks and the selected signals go to the DOLBY and MODE switches. Signals are then mode processed by the MODE switch and its associated circuit and applied to the tone control amplifier through the buffer amplifier and BALANCE and VOLUME controls. The bass and treble controlled signals from the tone control amplifier pass through the hi filter before they reach the main amplifier.

4.1 Mode Switch

MODE switch S002 has positions of MONO, 2 CH, DISCRETE, VARI-MATRIX, and SQ DECODER.

In the MONO position, all input signals are mixed together and delivered to all four channels.

In the 2 CH position, each pair of input signals right-front (RF) and right-rear (RR), and left-front (LF) and left-rear (LR) are mixed together. The resultant signals (RF + RR) and (LF + LR) are delivered to the pairs of RF and RR, and LF and LR channels, respectively.

In the DISCRETE position, each channel signal is separately routed to the corresponding channel.

In the VARI-MATRIX position, 2-channel stereo input signals are converted into quadraphonic signals through the vari-matrix circuit; the input right and left channel signals are fed directly to the LF and RF channels, while the signals to the LR and RR channels are synthesized from the 2-channel input signals under the control of the DIMENSION control. The LR and RR channel signal components are controlled by the DIMENSION control as shown below.

DIMENSION Control Setting	LR Output	RR Output
Minimum (FCCW)	LF + RF	RF + LF
Center	LF	RF
Maximum (FCW)	LF - RF	RF - LF

When the DIMENSION control is set to the minimum position the LR and RR channel signals become monophonic, to the center are stereophonic, and to the maximum are out of phase, thus providing vanished sound image positioning.

In the SQ DECODER position, signal sources encoded by the CBS SQ system are ideally decoded into 4-channel signals. Required for this operation is incorporation of the SQ Adaptor, Model SQA-1, into the Model 4400.

4.2 Balance Control

Signals from the buffer amplifiers are fed into the balance control circuit, in which the signals are controlled by three balancers: FRONT L-R, REAR L-R, and FRONT-REAR. By setting the FRONT-REAR balancer to the "FRONT" side and the FRONT L-R balancer to the "L" side, for example, only the front left channel is driven.

The balance control circuit is provided with the REMOTE CONTROL switch which makes the Model RC-4 Remote Control Box operative when set to the "REMOTE" position. In the "REMOTE" position the BALANCE and VOLUME controls on the Model 4400 become ineffective since signals are led to the Model RC-4. Balance and volume can be adjusted by the Model RC-4. Balance and Volume controlled signals are led to the tone control amplifier.

5. DOLBY NR UNIT

The Dolby units built in the Model 4400, which are two processors, allows you to monitor the Dolbyized recording sound with flat response from the loudspeakers during the Dolbyized recording on the tape recorder. The Dolby unit is inserted in front channels only.

An input signal coming to J601 (J602) is amplified by H601 (H602) and in the playback mode of operation, its output signal is fed to the high-cut filter and is further amplified by H603 and H605. In the record mode of operation, the signal magnified by the H602 is directly amplified by H604 and H606. The signal magnified by H603 and H605 (H604 and H606) comes to the resistance mixing circuit of R623 and R625 (R624 and R626) and to the phase inverting circuit of H607 and H609 (H608 and H610). The output signal is fed out from J607 (J608) to the TAPE MONITOR OUT Jack or amplifiers.

Encoding and decoding in the Dolby circuit are accomplished as follows. In the record mode of operation, the signal from J606 is led to J612 and is discriminated in frequency and level by the dynamic filter consisting of H612, resistor, and capacitor. The discriminated signal is then led to the amplifier of H614 and H616, and its output signal is fed back to the mixing circuit in phase, thus increasing the output level at J608, i.e., "encoded". In the playback mode of operation, a part of the output signal (J607) is fed to J611 and is discriminated in the frequency and level by the dynamic filter consisting of H611, resistor, and capacitor.

The discriminated signal is then fed to the amplifier of H613 and H615, and its output signal is fed back to the mixing circuit out of phase, thus decreasing the output level at J607, i.e., "decoded".

The diodes H626 to H629 function as a limiter. The attached "DOLBY PROCESSING CHART", page 18 will aid in the understanding of the operation of the Dolby circuit.

6. 400Hz TONE

The 400Hz tone signal is a 580mV, 400Hz sine wave fed to the FRONT and REAR TAPE MONITOR OUT jacks at any position of the DOLBY NR switch (with exception of the RECORD II position) and the SELECTOR switch.

The output signal of the 400Hz oscillator consisting of HL01 and HL02 is fed to JL02 and JL03, respectively, through the emitter follower HL03. The output levels at JL02 and JL03 are adjusted to 580mV and approximately 50mV, respectively.

The signal fed from the Dolby P.W. Board comes to JL04 and is rectified through HL06. The rectified output at JL06 is led to the meter M001.

7. DOLBY NR SWITCH

This switch sets the Dolby noise-reduction circuit for record or playback.

7.1 Dolby FM

This position is used for listening to Dolbyized FM broadcasts. The Dolby FM level has been pre-adjusted by RC05 and RC06.

7.2 Play

This position is used to play back a Dolbyized source (except FM).

7.3 Off

With this position, the Dolby circuit is by-passed and the input signals are directly applied to both TAPE MONITOR OUT jacks and amplifiers.

7.4 Record I

For making a Dolbyized recording from an in-coming "flat" (non-Dolbyized) signal. When the MONITOR switch is in the SOURCE (out) position, the "flat" signal will be heard. When the MONITOR switch is in the TAPE (in) position, the "flat" signal will be heard after the Dolbyized signal from the tape has been decoded.

7.5 Record II

For making a "flat" (non-Dolbyized) recording from an in-coming Dolbyized signal.

Regardless of the position of the MONITOR switch, a "flat" signal will be heard.

8. RECORD LEVEL (L) (R)

These knobs control the record level of the signals to be recorded through the Dolby unit. Adjust the knobs so that the Level Meter pointers of the tape recorder do not exceed the OVU level.

9. PLAY CAL. (L) (R)

These knobs adjust the playback outputs from a tape deck to the proper Dolby level.

10. DOLBY FM PRESET LEVEL CONTROLS

These factory-adjusted controls govern FM output level to the Dolby circuit. These controls are for the use of a qualified technician only.

11. 400Hz TONE SWITCH

This is used for calibration of the record input level of the tape deck. When the switch is depressed, the built-in oscillator operates and a sine wave signal output of 580mV will be applied to the four TAPE MONITOR OUT jacks.

12. FM DE-EMPHASIS SWITCH

At present both normal and Dolbyized FM broadcast programs are being transmitted with a pre-emphasis time constant of 75 microseconds.

However if the Dolbyized FM broadcasting is approved by the F.C.C., this pre-emphasis time constant for Dolbyized FM broadcast will be changed to 25 microseconds. The FM DE-EMPHASIS switch provided on the rear of Model 4400 is used for switching the time constants. After the permission of Dolbyized FM broadcasting, set the switch to 25 μ S position. The DOLBY NR switch will automatically change the time constant to 75 μ S when the DOLBY NR switch is placed in other than DOLBY FM position (namely normal FM broadcast position). Thus, the de-emphasis time constant for each normal and Dolbyized FM reception will be correctly set.

13. HI-LOW FILTER AMPLIFIER

This hi-low filter amplifier consists of active components HH01 to HH08 which provide a slope attenuation response of 12dB per octave. The signal input to the filter amplifier is passed through a time-constant circuit PS01 comprising a low filter of 50Hz cutoff frequency and a second time-constant circuit comprising a high filter of 9KHz cutoff frequency and is fed to the active components. The active components including NPN- and PNP-type transistors form a direct-coupled amplifier.

14. POWER AMPLIFIER

This power amplifier is a completely direct-coupled amplifying circuit. The transistors H701 and H702, form the first stage of a differential amplifier, improving the DC stability. The transistor H705 is a current regulating circuit which further improves the DC stability. The transistor H707 and H708, which form the second stage of the differential amplifier, function as driver. The transistor H737 is a current regulating circuit and is the load circuit for H707. The transistors H713 and H714 drive the transistors H003 and H004 which form the power output stage. The transistor H711 is a transistor biasing circuit.

Excessive current flow in the power output stage is detected by the resistor R761 and the resultant variation is applied to the transistors H717, H719 and H721 and cause them to conduct. This decreases the base drive current for H713 and H714. In this way the current flow in the power output stage (H003 and H004) is restricted to a safe predetermined value.

15. BTL (Balanced Transformer-less) CONNECTION

This power amplifier is designed to operate in either 2-channel or 4-channel modes, depending on the setting of the POWER MODE switch that incorporates phase-conversion and power switch for BTL connection.

With this switch placed in the 50Wx4 position, this unit operates as a 50W 4 channel amplifier. With the switch placed in the 125Wx2 position, the unit operate as a 125W 2 channel amplifier, in this case, the power output is obtained only from FRONT SPK terminals.

CAUTION: When testing this amplifier in the BTL mode (power mode switch set to 125 W x 2), it is mandatory that all test equipment connected to the speaker terminals be isolated from chassis and power line grounds. Additionally, the common or negative (-) speaker terminals of the amplifiers must not be connected together by common leads of the test equipment. **DO NOT GROUND ANY OF THE SPEAKER LEADS.**

16. POWER SUPPLY CIRCUIT

- 16.1 Power source for tuner (+13.5V) and stereo beacon (+12V) is zener-regulated (H808) and then filtered by a transistor ripple filter circuit consisting of H818.
- 16.2 Power source for MPX Pre-Amp., Phono-Amp., Pre-Amp. and Buffer/Pre-Amp. (+35V) is fed through a series-regulator circuit consisting of H812.
- 16.3 Both DC plus and minus 14V for the first differential of scope amplifiers are zener-regulated by two zener diodes, H807 and H809, respectively.
- 16.4 DC plus 200V for collector circuit of the vertical and horizontal of scope amplifier and DC minus 600V for CRT's anode are fed by the power supply circuit on P800.

17. AUDIO TROUBLE ANALYSIS

- 1. Excessive line consumption
 - a. Check for shorted transistors H001 through H008.
 - b. Check for shorted transistors H713 through H716.
 - c. Check L003 for short.
- 2. No line consumption or zero bias
 - a. Check line cord, fuse, shorted H711 & H712, H727 & H728.
 - b. Check for open rectifiers H801~H806 or open L003.
- 3. Excessive hum and noise level
 - a. Check filter capacitors C002, C003, C709, C710, C713, C714, C715 & C716.
 - b. Check for shorted transistor H812 and H813.
- 4. Parastic oscillation
 - a. Check for defective capacitors, C002, C003, C705, C706, C707, C708, C717, C718, C719, C720, C721, C722, C723 & C724.
- 5. Improper clipping
 - a. Check for proper adjustment of R721 and R722.

18. SCOPE DISPLAY CIRCUIT

Please, refer to the operating manual on general operating instructions for "SCOPE DISPLAY".

18.1 AM Tuning Display

AM signal strength and the correct tuning point are displayed on the scope through the following signal routine;

Rectified DC output at Pin Terminal J151→SELECTOR switch→TUNING DISPLAY switch→RT06 (270KΩ)→Pin No. 11 of J034→H904 vertical amplifier.

18.2 FM Tuning Display

FM signal strength and correct center tuning signals are applied to the oscilloscope's vertical and horizontal deflection plates through the following routines;

- a. Rectified DC output for FM signal strength at the Pin Terminal J209→Pin Terminal J315 →R373 (33K Ω)→H316 buffer amplifier→R374 (trimming resistor)→Pin Terminal J316→SELECTOR switch→TUNING DISPLAY switch→RT06 (270K Ω) Pin No. 11 of J034→H904 Vertical amplifier.
- b. DC plus and minus output for center tuning at the Pin Terminal J204→Terminal J039→R027 (68K Ω)→Pin Terminal JT06→Trimming resistor RT10 (50K Ω) →TUNING DISPLAY switch→RT07 (270K Ω)→Pin No. 3 of J034 H902 Horizontal amplifier (for center tuning).

Note 1. CT03 is filtering capacitor for audio signals

Note 2. For easy-to-see spot display, the display spot is modulated to have a slight length in vertical direction for FM tuning or in horizontal direction for AM tuning. This is done by applying a small amount of AC voltage for pilot lamps to the vertical (for FM) or Horizontal (for AM) amplifier input terminal Pin No. 9 or Pin No. 6 of J034 respectively.

AC voltage for pilot lamps→RT05→CT01→TUNING DISPLAY switch→SELECTOR switch→Pin No. 6 of J034 (for AM) or Pin No. 9 of J034 (for FM)

Note 3. RT09 is the DC bias adjusting resistor which corrects the spot position at no signal.

18.3 FM Multi-Path Display

The multi-path display circuit is almost the same as the FM TUNING DISPLAY circuit except the following:

- a. AC voltage for tuning spot modulation is cut off (RT05 and CT01 are disconnected) from the circuit by depressing the MULTI-PATH push switch.
- b. Audio signal pass filter (CT03) is cut off, this means audio signals developed at J204 are applied to the horizontal amplifier.

The vertical signal which contains multi-path information is the same as that of signal strength and supplied to the R374 through the pin terminal J209.

19. SCOPE CIRCUIT DESCRIPTION

19.1 Vertical Amplifier

The vertical amplifier consists of two stages of direct-coupled differential amplifiers, the first stage using two FETs (H903 and H904) and the second two transistors (H907 and H908).

It amplifies both AC and DC signals with very high stability.

The first differential amplifier operates as a source follower and no voltage gain is obtained.

The signal passed the first stage is directly fed to the second stage and amplified. The gain of this stage is 47dB for DC signal and 39dB for AC signal. The finally amplified signal is then applied to the oscilloscope tube.

- * R918 is a gain adjusting resistor and should be set for the gain of 234mV/cm. (at 1KHz, 2 CH DISPLAY position)
- * R910 is provided for adjusting DC balance between H903 and H904 and should be set so that the voltage difference between the source terminals of H903 and H904 is less than 0.05 volt with vertical centering control knob placed in its mechanical center.

19.2 Horizontal Amplifier

The circuitry of horizontal amplifier is almost the same as that of the vertical amplifier.

- * R917 is gain adjusting resistor and should be set for 234mV/cm (at 1KHz, 2 CH DISPLAY position).
- * R909 is the DC balance control between H901 and H902 and should be set so that the voltage difference between source terminals of H901 and H902 is less than 0.05 volt with horizontal centering control knob placed in its mechanical center.

20. TROUBLE SHOOTING OF OSCILLOSCOPE CIRCUIT

20.1 Symptom: No spot obtained

If no spot is obtained with CENTERING knobs (V and H) placed in their mechanical center and BRIGHT control on the rear panel at maximum, there would be defects in the CRT's circuit, vertical and/or horizontal amplifier. To localize the defects proceed as follows:

- a. Short both collector terminals of H907 and H908, and if the spot appear the vertical amplifier would be defective.
- b. Short both collector terminals of H905 and H906, and if the spot appear the horizontal amplifier would be defective.
- c. If no spot is still obtained, the CRT circuit would be defective.

20.2 Symptom: Blurred spot

First adjust FOCUS control on the rear panel and if no sharp spot is obtained, check whether the voltage between cathode of CRT (No. 3 terminal) and plate (No. 4 terminal) can be varied from 50V to 250V or not by adjusting FOCUS control on the rear panel. If the voltage varies within the limit above, the oscilloscope circuit is normal. Please, try to replace the CRT with new one.

CAUTION

1. Do not leave the scope turned on with BRIGHT control set maximum.

Do not make the spot left for a long time with its brightness maximum and its focus pin-pointed to avoid possible desensitivity of the phosphor. In the case where the scope has to be turned on for a long time, decrease the brightness of the spot. Turn the scope off when not in use.

2. High Voltage, Danger

When removing the top and/or bottom cover, always remove the power cord from the AC outlet to avoid possible electrical shock from high voltage for oscilloscope circuit.

3. Do not place the set (CRT) in a powerful magnetic field.

If placed, the electron beam in the CRT will be bent and the spot is shifted from the correct position. The trace may also be distorted.

21. TEST EQUIPMENT REQUIRED FOR SERVICING

Table 1 lists the test equipment required for servicing the Model 4400 Receiver.

Item	Manufacturer and Model No.	Use
AM Signal Generator		Signal source for AM alignment.
Test Loop		Used with AM Signal generator.
FM Signal Generator	Less than 0.3% distortion	Signal source for FM alignment.
Stereo Modulator	Less than 0.3% distortion	Stereo separation alignment trouble shooting.
Frequency Counter		MPX Oscillator adjustment (VCO).
Audio Oscillator	Weston Model CVO-100P, less than 0.02% residual distortion is required.	Sinewave and squarewave signal source.
Oscilloscope	High sensitivity with DC horizontal and vertical amplifiers.	Waveform analysis and trouble shooting and ASO alignment.
VTVM	With AC, DC, RF range	Voltage measurements.
Circuit Tester		Trouble shooting.
AC Wattmeter	Simpson, Model 380	Monitors primary power to Amplifier.
AC Ammeter	Commercial Grade (1-10A)	Monitors amplifier output under short circuit condition.
Line Voltmeter	Commercial Grade (0-150V AC)	Monitors potential of primary power to amplifier.
Variable Autotransformer (0-140V AC, 10 amps)	Powerstat, Model 116B	Adjusts level of primary power to amplifier.
Shorting Plug	Use phono plug with 600 ohm across center pin and shell.	Shorts amplifier input to eliminate noise pickup.
Output Load (8 ohms, $\pm 1\%$ 150W)	Commercial Grade	Provides 8-ohm load for amplifier output termination.
Output Load (4 ohms, $\pm 1\%$ 150W)	Commercial Grade	Provides 4-ohm load for amplifier output termination.

Table 1. Test Equipment Required for Servicing

22. SCOPE DISPLAY ALIGNMENT

- 22.1 Turn the SELECTOR switch to the "CD-4/AUX" position.
- 22.2 Depress both SCOPE DISPLAY switches "ON" and "AUDIO DISPLAY".
- 22.3 Adjust two CENTERING knobs to bring the spot into the center of small circular.
- 22.4 Adjust "BRIGHT" control (R022) on the rear panel to make the brightness of the spot dimmer.
- 22.5 Adjust "FOCUS" control, (R023) to make the spot smaller and more circular.

- 22.6 Feed in 775mV (1KHz) to the "CD-4/AUX INPUTS, FRONT R" jack and adjust R917 (HORIZ) to obtain a horizontal deflection of about 3.3cm, then connect the same input voltage to the "FRONT L" jack and adjust R918 (VERT) for the same vertical deflection.
- 22.7 Set both the centering knobs at their mechanical center, and adjust R909 (HORIZ) and R910 (VERT) to bring the spot into the center of small circle.

23. AM TUNING DISPLAY ALIGNMENT

- 23.1 Depress both SCOPE DISPLAY switches "ON" and "TUNING" and SELECTOR switch to "AM".
- 23.2 Adjust RT09 to bring the spot on the lower center of the base line with no station tuned in.

24. FM TUNING DISPLAY ALIGNMENT

- 24.1 Depress both SCOPE DISPLAY switches "ON" and "TUNING" and SELECTOR switch "FM".
- 24.2 Connect FM signal input of 100K μ V (98MHz, 400Hz, 30% Mod.) to the FM ANTENNA terminal and adjust R374 so that the spot does not frame out.
- 24.3 FM Multipath display alignment: Adjust RT10 to obtain full deflection of the trace within both side marks, applying FM signal (1K μ V, 400Hz, 100% Mod.) to the FM ANTENNA terminals.

25. AM ALIGNMENT PROCEDURE

25.1 AM IF Alignment

1. Connect a sweep generator to the J153 and an alignment scope to the test point ③.
2. Rotate each core of IF transformer L153 and L154 for maximum height and flat top symmetrical response.

25.2 AM Frequency Range and Tracking Alignment

1. Set AM signal generator to 525KHz. Turn the tuning capacitor fully closed (place the tuning pointer at the low end.) and adjust the oscillator coil L152 for maximum audio output.
2. Set the signal generator to 1650KHz. Place the tuning pointer in the high frequency end and adjust the oscillator trimmer on the oscillator tuning capacitor for maximum audio output.
3. Repeat the step 1 and 2 until no further adjustment is necessary.
4. Set the generator to 600KHz and tune the receiver to the same frequency and adjust a slug core of AM ferrite rod antenna and RF coil L151 for maximum output.
5. Set the generator to 1400KHz and tune the receiver to the same frequency and adjust both trimming capacitors of antenna and RF tuned circuit for maximum output.
6. Repeat the step 4 and 5 until no further adjustment is necessary.

Note: During tracking alignment reduce the signal generator output as necessary to avoid AGC action.

25.3 AM Signal Strength Display Adjustment

Set the AM Signal generator to 1000KHz with 100dB/m, and adjust R152 so that the spot may meet upper mark.

26. FM ALIGNMENT PROCEDURE

1. Connect an FM signal generator to the FM ANTENNA terminals and an oscilloscope and an audio distortion analyzer to the TAPE MONITOR OUT jacks on the rear panel.
2. Set the FM SG to 87.5MHz and provide about 3 to 5 μ V. Place the tuning pointer at the low frequency end by rotating the tuning knob and adjust the core of oscillator coil L105 to obtain maximum audio output.

3. Set the FM SG to 108.5MHz and provide about 3 to 5 μ V output. Rotate the tuning knob and place the tuning pointer at the high frequency end and adjust the trimming capacitor C106 for maximum output.
4. Repeat the step 2 and 3 until no further adjustment is necessary.
5. Set the FM SG to 90MHz and tune the receiver to the same frequency. Decrease signal generator output until the audio output level decreases with the decreasing generator output. Adjust the antenna coil L101, RF coil L102, L103 and L104 and IF transformer L106 for minimum audio distortion.
6. Set the FM SG to 106MHz and tune the receiver to the same frequency. Adjust the trimming capacitors of antenna and RF tuning circuits for minimum distortion (C102, C103, C104, C105).
7. Repeat the step 5 and 6 until no further adjustment is necessary.
8. Connect a VTVM (with DC 1V range) across the pin terminal J204 and common ground. Adjust the secondary core (upper) of discriminator transformer L201 so that the VTVM indicates null reading (zero reading) at no signal. Set the FM SG to 98MHz and increase its output level to 1K μ V and tune the receiver to the same frequency so that the VTVM gives null reading. Next adjust the primary core (lower) of L201 for minimum distortion. (Scope display can, of course, be used as tuning indicator instead of the VTVM, if the scope unit has been correctly adjusted as instructed in the SCOPE DISPLAY ALIGNMENT.)
9. Set the FM SG to 98MHz with 100K μ V, and adjust R374 so that signal strength indicator spot just reaches upper mark.

Figure 2. Dial Stringing

26.1 Stereo Separation Alignment

1. Set the FM SG to provide $1K\mu V$ at 98MHz. Tune the receiver to the same frequency so that the tuning indicator spot indicates its center. Then turn off the modulation of the FM SG, connect a frequency counter to test point J310 (point ©) and adjust R311 so that the frequency counter may a precisely read 19KHz.
2. Modulate the FM SG with stereo composite signal consisting of only L or R channel (of course a pilot signal must be included).
3. Adjust the trimming resistor R301 for maximum and same separation in both channels.

26.2 Muting Circuit Alignment

1. Connect a VTVM to the tap of the resistor R363 and adjust the resistor R363 until the meter reads 0.75V DC at no signal.
2. Set the FM SG to provide $1K\mu V$ at 98MHz and tune the receiver to the same frequency correct.
3. Turn on MUTING push-switch. Shift the FM signal generator frequency to plus and minus and note both plus and minus shifted frequencies at which undesirable audio side responses are muted out. Adjust the R363 so that the same shifted frequencies mute the undesirable side response.
4. Adjust R362 for preferred frequency shift at which the muting circuit operates.

27. AUDIO ADJUSTMENT

1. Connect a VTVM to No. 11 of J036(+) and No. 9 of J036(-) and adjust the trimming resistor R739 until the VTVM reads 12mV DC. For the other channel connect the VTVM to No. 33 of J036(+) and No. 35 of J036(-) and adjust the R740 for the same reading.
2. Connect a VTVM to No. 13 of J036(+) and No. 15 of J036(-) and adjust the trimming resistor R721 until the VTVM reads 0V DC. For the other channel connect the VTVM to No. 31 of J036(+) and No. 29 of J036(-) and adjust the R722 until the VTVM reads 0V-DC.

28. AUTOMATIC VOLTAGE REGULATOR ADJUSTMENT

Connect a VTVM to JM03(+) and JM04(-) and adjust R810 until the VTVM reads 35V under no signal condition.

29. DOLBY ALIGNMENT PROCEDURES

For adjustment of the Dolby unit, an alignment fixture should be built up based on the Fig. 3 circuit diagram. Then, using the alignment fixture proceed as follows.

1. A) Set the REC/PB switch to REC, the DOLBY ON/OFF switch to OFF (close), and the FET GATE switch to OFF (close).
 B) Adjust the semi-fixed resistor R654 until the source voltage for the FET (H612) becomes maximum (positive).
 C) Feed in 5KHz at a level to give 17.5mV at J606.
 D) Note signal level obtained at the OUTPUT terminal.
 E) Set the DOLBY ON/OFF switch to ON (OPEN) and adjust gain control (R660) for a 10 ± 0.25 dB rise at the OUTPUT terminal.
 F) Note level at OUTPUT terminal with DOLBY ON/OFF switch ON.
 G) Set the FET GATE to ON and adjust low control (R654) for a 2 ± 0.25 dB drop at output terminal.
 H) Check the level setting at Step C) to G)
2. A) Set the REC/PB switch to PB, the DOLBY ON/OFF switch to OFF (close), and the FET GATE switch to OFF (close).
 B) Adjust the semi-fixed resistor R653 until the source voltage for the FET (H611) becomes maximum (positive).

- C) Feed in 5KHz at a level to give 44mV at J605.
 D) Note signal level obtained at the OUTPUT terminal.
 E) Set the DOLBY ON/OFF switch to ON and adjust gain control (R659) for a 10 ± 0.25 dB fall at the OUTPUT terminal.
 F) Note level at OUTPUT terminal with DOLBY ON/OFF switch ON.
 G) Set the FET GATE to ON and adjust low control (R653) to give a rise of 2 ± 0.25 dB at the OUTPUT terminal.
 H) Check the level setting at Step C) to G).
3. For the level adjustment, set the DOLBY NR switch and SELECTOR switch to the RECORD I and CD-4/AUX positions, respectively, and use the TAPE MONITOR OUT jack for the output signal. By setting the 400Hz TONE pushswitch "in", the 400Hz sine wave is fed out. Adjust the semi-fixed resistor RL11 for 580mV of the sine wave output voltage in both R and L channels. Then, connect the 400Hz 580mV signal at TAPE 1 R and L OUTPUT Jacks to the TAPE 1 R and L INPUT Jacks with external shielded leads. Place "MONITOR" switch in TAPE 1 position. Adjust the semi-fixed resistors RL28 and RL29 until the DOLBY LEVEL meter indicates Dolby level. Change over the METER switch, and perform this adjustment for both R and L channels.
- Next adjust the semi-fixed resistor RL12 for 580mV output level when the DOLBY NR switch is set to the OFF position. Check this output level after the adjustment of the level setting semi-fixed resistors RL11 and RL12. The output level must be precisely 580mV since it is a reference voltage level in the Dolby circuit.

30. ALIGNMENT PROCEDURES FOR DOLBY FM PRESET LEVEL CONTROLS

Connect an FM signal generator to the FM antenna. Set the modulation frequency and deviation of the FM signal generator to 400Hz and 50% (with PILOT carrier).

Set the FM signal generator to 98MHz and the DOLBY NR switch to the OFF position. Turn the Tuning knob on Model 4400 unit it tunes to the 98MHz signal from the FM signal generator.

Then, set the DOLBY NR switch to the DOLBY FM position, and adjust the FM preset level controls RC05 and RC06 so that the DOLBY LEVEL meter may point the Dolby FM level. Change over the METER switch, and perform this adjustment for both R and L channels.

Figure 3. Dolby Alignment Fixture Schematic

31. EXPLANATION OF THE DOLBY PROCESSING CHART

This chart shows the condition of the signals available at the speakers (SPKRS) and at the TAPE MONITOR OUT terminals as a function of different control settings.

To understand the chart refer to the symbols below:

- 
— Represents a signal which has not been applied to either Record or Playback Dolby circuits. The relative amplitudes of all audio frequencies remain unaltered at all levels.
- 
— Represents a signal which has been processed by the Dolby Record circuit. The relative amplitude of the high frequencies is increased at low signal levels.
- 
— Represents a signal which has been processed by the Dolby Playback circuit. The relative amplitude of the high frequencies is decreased at low signal levels.
- 
— Represents a signal which has been processed by both the Record and the Playback Dolby circuits.

These circuits are complementary. Therefore, relative amplitudes of all audio frequencies are restored to their original values.

TECHNICAL SPECIFICATIONS

PREAMPLIFIER SECTION

Dynamic Range	Phono input: 96dB above 1.5 μ V equivalent noise input
Note:	Dynamic Range is the ratio in dB of phono overload (100mV) to equivalent input noise (1.5 μ V).
Input Sensitivity and Impedance	Phono: 1.8mV, 47 Kohms High Level: 180mV, 100 Kohms
Pre-out Output Level	1V
Pre-Out Output Impedance	900 ohms
Phono Frequency Response	30Hz to 15KHz \pm 1dB (RIAA)
Noise-Aux	-80dB
Tone Controls	Treble: \pm 10dB at 15KHz Bass: \pm 10dB at 50Hz Mid-Range: \pm 6dB at 700Hz
Filters	Hi Filter: 9KHz, 12dB per octave Low Filter: 50Hz, 12dB per octave
Loudness Compensation	7dB at 100Hz 4dB at 10KHz

AMPLIFIER SECTION

Headphones Output	.047V into 8 ohms at rated distortion
Input Sensitivity for MAIN in Front/Rear	1V
Power Output	200 Watts into 8 ohms (50W/channel x 4) 250 Watts into 8 ohms (125W/channel x 2)
Total Harmonic Distortion	At or below rated power, 20Hz to 20KHz Less than 0.15%, typically 0.05% including preamplifier (AUX)
IHF Power Bandwidth	8Hz-70KHz
Frequency Response	\pm 2dB, 5Hz to 70KHz \pm 1dB, 10Hz to 30KHz
Damping Factor	2-channel Mode: 40 at 20Hz 4-channel Mode: 50 at 20Hz

FM SECTION

Quieting Slope	1.8 μ V for 30dB, 5 μ V for 55dB 10 μ V for 60dB, 50 μ V for 70dB
Ultimate Quieting	50 μ V for 70dB
Selectivity	Alternate channel, better than 75dB
Capture Ratio	1.5dB
Muting Threshold	Muting threshold variable from 8 μ V to 35 μ V
Stereo Separation	42dB at 1KHz, 27dB at 15KHz
Total Harmonic Distortion	Stereo: Less than 0.3% Mono: Less than 0.2%
Frequency Response	\pm 1dB, 30Hz to 15KHz
Total Spurious Rejection	Better than 95dB
Image Rejection	Better than 90dB
AM Suppression	Better than 60dB
IF Rejection	Better than 100dB
Antenna Impedance	300 ohm Balanced, 75 ohm unbalanced
Quadradial Output	300mV, 15 Kohms for \pm 75KHz Dev.

AM SECTION

AM Sensitivity	20 μ V
